ABSTRACT

To analyze the available scientific evidence on the effectiveness of green tea and its products in the prevention of dental caries. A broad literature search was performed using COCHRANE CENTRAL, MEDLINE, GOOGLE SCHOLAR, EBSCO, PROQUEST for online search and hand search was performed in the central library of the institute. Articles that satisfied the inclusion criteria with description of randomized clinical trials regarding green tea in the prevention of dental caries were included. Initial search resulted in 196 articles; Our final review included 5 studies. Of these 2 studies evaluated both streptococcus mutans and lactobacillus, 1 study evaluated streptococcus mutans separately, 1 study evaluated salivary fluoride concentration, 1 study evaluated caries increment of the green tea polyphenol. Among the five studies two studies showed a significant reduction in the levels of streptococcus mutans. One study showed significant reduction in the levels of lactobacillus. One study showed that there was significant increase in the fluoride level. One study showed that the green tea and its extracts has an inhibitory effect on dental caries. With the constraints of limited available literature green tea and its extracts had a inhibitory effect on dental caries. But still further studies are recommended.

Key words: Tea, Polyphenols, Dental Caries

INTRODUCTION

Dental caries is an important public health predicament. The unique characteristic of dental diseases is that they are universally prevalent and do not undergo diminution or termination if untreated and require technically demanding expertise and time consuming professional treatment. The risk factors should be comprehensively studied so that the occurrence of dental caries can be prevented.[1]

Many attempts have been made to eliminate S. mutans from the oral flora, antibiotics such as penicillin; ampicillin, tetracycline, erythromycin and vancomycin are very effective in preventing dental caries in vivo and in vitro. However, their excessive use can result in alterations of the oral and intestinal flora and cause undesirable side-effects.[2]

Tea is an infusion of the leaves of the Camellia sinensis plant. Which grows mainly in South East of Asia. Tea is the most popular beverage in the world after water, Drinking Green Tea, a suggestive of health beverage is common for more than 2000 years. In the last couple of year there is a growing interest in green tea in the western world due to scientific findings that show the health potentials of the beverage. Green tea has a unique composition, which includes proteins such as cellulose, pectin, glucose, fructose and sucrose and lipid components: linoleic and linolenic acids and sterols such as stigmastanol. Besides macronutrients, green tea also includes vitamins, pigments such as chlorophyll and carotenoids.[3]

Other important green tea components are the polyphenols which constitute the most interesting group amongst the components of green tea leaves. The main polyphenols in green tea are catechins. The four main catechins are epigallocatechin a 3 gallate (EGCG), epigallocatechin (EGC), epicatechin 3 gallate (ECCG), epicatechin (EC). Research suggests that green tea has an antioxidant property. Green tea is a non fermented tea and contains more catechins. Catechins are in vitro and invivo strong...
antioxidants. These catechins possess antimutagenic, antidiabetic, anti-inflammatory, antibacterial and anti viral properties.[4]

Green Tea can be used as antioxidant, antimutagenic and anticiarcigenic. It is used to improve oral health including dental caries, periodontal disease and tooth loss, abolition of halitosis, oral malignancy prevention and regression. It has an antihypertensive effect and it reduces cardio vascular disease risk. It helps in body weight control and also helps in glucose tolerance and insulin sensitivity.

Polyphenols constitute one of the most common and widespread groups of substances in plants. The main sources of polyphenols present in the human diet are plants like tea, coffee, cereals and fruits. Subsequent invitro studies on plant extracts suggest an activity against several metabolic activities of mutans streptococci, resulting in decrease in growth and virulence. Smullen et al have shown that extracts from unfermented green tea have a bacteriostatie effect on streptococcus mutans.

Studies on the development of anti plaque agents in the prevention of dental caries have investigated the effect of some tea preparations and their individual components on the glucan synthesis catalyzed by glucosy transferase from mutans streptococci. Extracts of green tea showed appreciable inhibition in the synthesis of insoluble glucan. A point that should be mentioned is that the invitro property of green tea has also been much investigated previously, but in vivo evidence able to establish its real contributions to caries reduction is not consistent for these reasons a non invasive method of invitro investigation has been developed.[5]

AIM
The Aim of the study is to systematically analyzed the available Scientific evidence on the effectiveness of Green Tea and its products in the prevention of Dental caries.

METHODS
Focused Question: What is the clinical impact of green tea extract in prevention of dental caries?

Selection Criteria:
Inclusion Criteria:
Type of Studies : Randomized clinical trials.
Subjects: Any one who received green tea or green tea extract as a preventive agent for dental caries. Randomized clinical trials were included only when they
1) Assess the in-vivo role of green tea extract on caries lesion development and in reducing Streptococcus mutans and Lactobacillus.
2) Consider human studies without any medical condition.
3) Were published in English language.
4) Involve any extract of green tea
Exclusion Criteria:
1) All in-vitro studies.
2) All studies not focusing on green tea extract for caries prevention.
3) All studies where green tea extract is used for other reasons were excluded.

Types of outcome measures:
- Levels of Streptococcus Mutans and Lactobacillus.
- Levels of salivary fluoride concentration.
- Caries increment of green tea.

Search Strategy: The main important available data bases searched are MEDLINE, GOOGLE SCHOLAR, EBSCOHOST, PROQUEST and COCHARANE CENTRAL.

The search was focused on seeing the keywords: green tea, prevention of dental caries, Streptococcus mutans, Lactobacillus which were used as isolated or in combinations using different Boolean Operators. Comparisions of different searches were carried out to delete the repeated studies. Then abstracts of all available articles were examined. All studies, which appeared to meet the inclusion criteria, were obtained in the full text format & they go for validity assessment. Application of the Cochrane Collaboration tool for evaluating the risk of bias was done. Then selected were grouped into high risk bias and low risk bias articles.

RESULTS
The initial search resulted in 196 articles. After analyzing the full text from clinical trials duplicating articles (90) were excluded. After that exclusion of non clinical trials (74) has been done. Final assessment of inclusion criteria for clinical trials is 32. After analyzing the full test from 32 clinical trials, 27 articles were excluded because they did not fulfill all the selection criteria. Our final review included 5 articles.

Levels of streptococcus mutans and lactobacillus: -
Thomas A et al (2015) evaluated the count of streptococcus mutants, lactobacilli. It was found that against S. mutans and lactobacilli, after chlorhexidine mouth rinse, garlic with lime mouth rinse was found to be significantly more effective than sodium fluoride (p=0.053, P=0.001), fluoride with essential oils (P<0.001, P<0.001), alum (P<0.001, P<0.001), and green tea (P<0.001, P<0.001) mouth rinses. Chlorohexidine mouth rinse was significantly better than green tea mouth rinse. Mean zone of inhibition of chlorohexidine against streptococcus mutants is higher when compared to green tea. Mean zone of inhibition of chlorohexidine against lactobacillus (19.5) is significantly higher than green tea (11.167). However, further studies are needed in this field.[7] Ibrahim Awadalla H et al (2011) evaluated the count of streptococcus mutants. There was a statistically significant difference (p<0.001) in means of Sm count in saliva after 7 days follow up between cases (normal oral hygiene + 2% of green tea) and controls (mouth wash without an active ingredient) concerning their response to intervention by rinsing with 2% green tea solution. There was a statistically significant difference (p<0.001) in means of Sm count in plaque after 7 days follow up between cases and controls concerning their response to intervention by rinsing with 2% green tea solution.

Attrition bias

Incomplete outcome data
Assessments should be made for each main outcome (or class of outcomes).

Describe the completeness of outcome data for each main outcome, including attrition and exclusions from the analysis. State whether attrition and exclusions were reported, the numbers in each intervention group (compared with total randomized participants), reasons for attrition / exclusions where reported, and any re-inclusions in analyses performed by the review authors.

Reporting bias
Selective reporting

State how the possibility of selective outcome reporting was examined by the review authors, and what was found.

Other bias
Other sources of bias

State any important concerns about bias not addressed in the other domains in the tool. If particular questions/entries were pre-specified in the review’s protocol, responses should be provided for each question / entry.

Result

Both groups were statistically significant. Experimental group showed a statistically significant reduction in colony counts of mutans streptococci and lactobacilli. Chlorhexidine mouth rinse was significantly better than green tea mouth rinse. Chlorhexidine mean zone of inhibition (18.667) is higher when compared to green tea (11.167) against streptococci mutans.

There was a significant difference among study group (normal oral hygiene + 2% of green tea) and control group (mouth wash without an active ingredient) concerning streptococci mutans.

DISCUSSION

There was a reduction in GBI between cases and controls and this difference was statistically significant (p<0.001) concerning gingival bleeding index (GBI) among their response to intervention by rinsing with 2% green tea solution after 7 days follow up. This study supports the effectiveness of green tea as anti bacterial and anticariogenic material.\(^8\) Ferrazanno G et al (2011) evaluated the count of streptococcus mutans and lactobacilli in saliva. Green tea polyphenols was used in the experiment. The experimental group showed a statistically significant reduction in colony counts of mutans streptococi and lactobacilli relative to the control group (mouth rinse other green tea). These findings showed the efficacy of a green tea extract against cariogenic oral flora, opening a promising avenue of clinical applications in the preparation of specific and natural anticariogenic remedies.\(^9\)

Levels of salivary fluoride concentration:

Suyama E et al (2011) evaluated Salivary fluoride concentrations in green tea and fluoride content of remineralized enamel. It was found that the peak salivary fluoride concentration was 3.93 \(\pm\) 1.28 ppm (mean \(\pm\) SD). The elevated salivary fluoride concentration resulted in a higher fluoride concentration of 656 \(\pm\) 95 ppm in the remineralized region versus 159 \(\pm\) 26 ppm for placebo gum (p<0.001). The fluoride content in the FCG group was higher than in the placebo group (gum which doesn’t contain fluoride). After an acid challenge, the FCG group was lower than the placebo gum group. Both were statistically significant. FCG produced a superior level of remineralization and acid resistance as compared to the placebo gum. The results suggest that regular use of FCG is useful for preventing dental caries.\(^5\)

One study evaluated the salivary fluoride concentrations in green tea. It was found that both groups were statistically significant study group (chewing gum containing fluoride extracted from green tea) placebo group (gum which doesn’t contain fluoride). The fluoride content in the FCG group was higher than in the placebo group.\(^5\)

Cariostatic Potential of Green Tea:-

Ying Tao D et al (2013) evaluated the cariostatic potential of the chewing gum containing tea polyphenol. It was found that the mean DMFT increment was 0.17 for the polyphenol gum group, 0.60 for the control gum (gum not containing polyphenol), and 1.15 for the no gum group. Children who chewed gum containing tea polyphenol had a significantly lower mean DMFS increment over the 24 – month period than did the other two groups (p<0.05). The caries – free rate in the polyphenol gum group was significantly higher than that in the other two groups (p<0.05) after two years. These finding indicated that the oral application of chewing gum with tea polyphenol has an inhibitory effect on dental caries.\(^6\)

3 Studies evaluated the count of Streptococcus mutans. Two studies evaluated the count of lactobacillus. Two studies showed a significant reduction in the levels of streptococcus mutans. One study showed significant reduction in the levels of lactobacillus.\(^5,6,8,9\)
There are many well documented health benefits of Green Tea including prevention of dental caries. Thus, goal of this systematic review was to determine whether the use of Green Tea has clinical beneficial effects in the prevention of dental caries. Subjects who received Green Tea or Green Tea extract as a preventive agent for dental caries were the study subjects. Studies which assess the in vivo role of Green Tea extract on caries lesion development and in reducing streptococcus mutans and lactobacillus were included in this study. Among five studies which satisfied the inclusion criteria two studies (Gianmario F et al, Thomas A et al) evaluated streptococcus mutans and lactobacillus levels in saliva. After experimentation with Green Tea extracts, among the two studies only one study showed significant reduction in streptococcus mutans and lactobacillus. Green Tea extract presented a significant lowering of levels of streptococcus mutans and lactobacillus compared with subjects using placebo. This is probably due to the antibacterial properties of polyphenols associated with the inhibition of adherence of bacterial cells to tooth surfaces.6,7 One study (Ibrahim Awadalla H et al) evaluated only streptococcus mutans levels in saliva. After exposure to Green Tea extracts which showed a significant reduction in streptococcus mutans level supporting Green Tea as anticariogenic agent. The release of active ingredient from Green Tea (Catechins) reduces plaque acidity and preserve PH towards neutrality which represented unfavourable medium for streptococcus mutans as the level of bacteria in saliva and plaque is related to caries development.8,9 One study (Suyama E et al) evaluated salivary fluoride and fluoride content of remineralized enamel. After exposure to chewing Gum extracted from Green Tea superior level of remineralization an acid resistance was demonstrated by fluoride containing Gum extracted from Green Tea compared to placebo. The promotion of remineralization and the acquisition of acid-resistant property of enamel was mainly due to fluoride ion released from the Fluoride chewing gum derived from Green Tea extract.5 One study (Ying Tao D et al) evaluated the caries increment of the Green Tea polyphenol. It was found that Green Tea and its extracts has an inhibitory effect on dental caries. The antibacterial effect of green tea extract had valuable anti-cariogenic activities including inhibitory effect on cariogenic bacteria by inhibiting the adherence of bacterial cells to the tooth surfaces. And also green tea catechins maintain the salivary pH at a normal range (6.2-7.5) which is not a favorable condition for cariogenic bacteria to flourish.8,9

CONCLUSION
The use of green tea extract for caries prevention showed promising results even though only few studies have demonstrated clear clinical outcomes. Therefore, the scientific evidence is still poor.

RECOMMENDATION
The results of this systematic review confirm that more studies are necessary to evaluate the efficacy of Green Tea with correct methodological design, without private funding in broader population samples and over longer periods of time. Comparative trials of different extracts of Green Tea would also be interesting.
